

Description

The μPD41416 is a 16,384-word by 4-bit dynamic N-channel MOS RAM designed to operate from a single +5 V power supply. The negative voltage substrate bias is internally generated; its operation is both automatic and transparent. The μPD41416 utilizes a double-polylayer, N-channel, silicon gate process which provides high storage cell density, high performance, and high reliability.

The μPD41416 uses a single transistor dynamic storage cell and advanced dynamic circuitry throughout, ensuring minimum power dissipation. Refresh is accomplished by performing RAS-only refresh cycles, hidden refresh cycles, or normal read or write cycles on the 128 address combinations of A₀-A₆ during the refresh period of 2 milliseconds.

Multiplexed address inputs permit the μPD41416 to be packaged in a standard 18-pin dual-in-line package for high system bit density.

Features

- 16,384-word × 4-bit organization
- Single +5 V power supply ± 10%
- Standard 18-pin plastic package
- CAS, \overline{OE} or early write mode to control D_{OUT} buffer impedance
- Low power dissipation,
 - Active (t_{RC} = min): 303 mW
 - Standby: 28 mW
- Read, write, read-write, read-modify-write. \overline{RAS} -only refresh, hidden refresh, and page mode capabilities
- 128 refresh cycles during 2 ms period

Performance Ranges

Device	t _{RAC}	t _{CAC}	t _{OEA}

Absolute Maximum Ratings

Voltage on any pin relative to GND	-1.0 V to +7.0 V
Storage temperature, T _{STG}	-55°C to 125°C
Short-circuit output current, I _{OS}	50 mA
Power dissipation, P _D	1.0 W

Comment: Exposing the device to stresses above those listed in Absolute Maximum Ratings could cause permanent damage. The device is not meant to be operated under conditions outside the limits described in the operational sections of the specification. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

Notes:

- (1) All voltages referenced to GND.
- (2) An initial pause of 100 μs is required after power-up followed by any 8 $\overline{\text{RAS}}$ cycles before proper device operation is achieved.
- (3) AC measurements assume $t_T = 5$ ns.
- (4) V_{IH} (min) and V_{IL} (max) are reference levels for measuring timing of input signals. Transition times are measured between V_{IH} and V_{IL} .
- (5) I_{CC1} , I_{CC3} and I_{CC4} depend on output loading and cycle rates. Specified values are obtained with the outputs open.
- (6) The minimum specifications are used only to indicate cycle time at which proper operation over the full temperature range ($T_A = 0^\circ\text{C}$ to 70°C) is assured.
- (7) Load = 2 TTL loads and 100 pF.
- (8) Assumes that $t_{RCD} \leq t_{RCD}(\text{max})$. If t_{RCD} is greater than the maximum recommended value shown in this table, t_{RAC} will increase by the amount that t_{RCD} exceeds the value shown.
- (9) Assumes that $t_{RCD} \geq t_{RCD}(\text{max})$.
- (10) $t_{OFF}(\text{max})$ and $t_{O EZ}(\text{max})$ define the time at which the output achieves the open circuit condition and are not referenced to V_{OH} or V_{OL} .
- (11) Operation within the $t_{RCD}(\text{max})$ limit insures that $t_{RAC}(\text{max})$ can be met. $t_{RCD}(\text{max})$ is specified as a reference point only. If t_{RCD} is greater than the specified $t_{RCD}(\text{max})$ limit, then access time is controlled exclusively by t_{CAC} .
- (12) t_{CRP} requirement should be applicable for $\overline{\text{RAS}}$, $\overline{\text{CAS}}$ cycles preceded by any cycle.
- (13) Either t_{RRH} or t_{RCH} must be satisfied for a read cycle.
- (14) These parameters are referenced to $\overline{\text{CAS}}$ leading edge in early write cycles and to $\overline{\text{WE}}$ leading edge in delayed write or read-modify-write cycles.
